**What Clinicians  
and Other Health  
Professionals  
Need To Know**

A website designed for  
**Primary care physicians**  
**Infectious disease specialists**  
**Staff of blood banks**  
**Public health professionals**  
**Other health care professionals**

# Hepatitis C

General Public

If you are searching for information on hepatitis because you believe that you, a family member, or someone you are associated with has hepatitis (or has been exposed to hepatitis) you should contact your doctor, your clinic, or your state or local health department.

If you are searching for general information on hepatitis, please refer to the Centers for Disease Control and Prevention (CDC) Hepatitis Branch website at <http://www.cdc.gov/hepatitis> or call our toll-free hepatitis hotline at 1-888-4HEPCDC or 1-888-443-7232.

## Course Information

*Hepatitis C: What Clinicians and Other Health Professionals Need to Know* is a web-based training course designed to guide clinicians as they face this public health threat. The text is based upon the *Recommendations for prevention and control of hepatitis C virus (HCV) infection and HCV-related chronic disease*.

Source: Centers for Disease Control and Prevention. MMWR 1998; 47 (No. RR-19)

### Course objectives

After completing this course you will be able to:

- Describe the natural history of Hepatitis C Virus (HCV) infection
- Describe the risk factors for acquiring HCV infection
- Describe serologic and laboratory tests to diagnose and evaluate patients with HCV infection
- Discuss treatment options for patients who have chronic hepatitis C
- Discuss the most effective methods to counsel patients who have HCV infection

### Target audience

*Hepatitis C: What Clinicians and Other Health Professionals Need to Know* course is intended for the following audiences

- Primary care physicians
- Infectious disease specialists
- Staff of blood banks
- Public health professionals
- Other health care professionals

### Course layout

The course topics are listed on the menu at the left. We have included study questions and case studies to assist you in learning and applying the information. The approximate range of time for completing the course is 2 hours.

### Development team

This content for this course has been developed by the following:

Hepatitis Branch  
Division of Viral and Rickettsial Diseases  
National Center for Infectious Diseases  
Centers for Disease Control and Prevention

Division of Media and Training Services  
Public Health Practice Program Office  
Centers for Disease Control and Prevention

# Hepatitis C

## Course Information

**Continuing education credit is available free of charge!**

### **Accreditation Council for Continuing Medical Education (ACCME)**

**CME:** CDC is accredited by the Accreditation Council for Continuing Medical Education (ACCME) to provide continuing medical education for physicians. CDC designates this educational activity for a maximum of 2.5 hours in category 1 credits towards the AMA Physician's Recognition Award. Each physician should claim only those hours of credit that he/she actually spent in the educational activity.

### **American Nurses Credentialing Center's Commission on Accreditation**

**CNE:** This activity for 3.0 contact hours is provided by CDC, which is accredited as a provider of continuing education in nursing by the American Nurses Credentialing Center's Commission on Accreditation.

### **International Association for Continuing Education and Training**

**CEU:** CDC is approved as an Authorized Provider of continuing education and training programs by the International Association for Continuing Education and Training and awards .25 continuing Education Units.

### **American Academy of Family Physicians (AAFP)**

This program has been reviewed and is acceptable for up to 2.5 prescribed credit hours by the American Academy of Family Physicians. Term of approval is from beginning distribution date of May 15, 2000, with option to request yearly renewal.

Physicians requesting CME from the American Academy of Family Physicians should file the appropriate documentation with the Academy. Any questions regarding this process should be referred to them.

### **Instructions for obtaining continuing education credit:**

To receive CME credits Call 1-800-41-TRAIN. You will receive a packet containing instructions, two optical scan forms, and a return envelope. You can expect to receive these materials within 2 weeks.

The next pages contain the questions for the evaluations. The evaluation questions will not be included in the aforementioned materials. You must complete the evaluation to receive CME credits. NOTE, there is **no** post-test requirement!

What Clinicians and Other  
Health Professionals Need to Know

Course # WB3037

1

**Goal:**

To provide up-to-date information on the prevention and control of hepatitis C virus (HCV) infection and HCV-related chronic disease.

**Objectives:**

After completing this course, participants will be able to:

- 1) Describe the natural history of hepatitis C virus (HCV) infection.
- 2) Describe the risk factors for acquiring HCV infection.
- 3) Describe the serologic and laboratory tests to diagnose and evaluate patients with HCV infection.
- 4) Discuss treatment options for patients who have chronic hepatitis C.
- 5) Discuss the most effective methods to counsel patients who have HCV infection.

1. What type of continuing education credit do you wish to receive?

\*\* Nurses should request CNE not CEU.

- A. CME for physicians
- B. CME for non-physicians
- C. CNE (Continuing Nursing Education)
- D. CEU (Continuing Education Unit)
- E. AAFP (American Academy of Family Physicians) CME
- F. Not participating in the course for credit

2. Are you a...

- A. Physician
- B. Nurse
- C. Physician Assistant
- D. Nurse Practitioner
- E. Health Educator
- F. Other

3. Which of the following best describes your work setting?

- A. Private Practice
- B. City/County/State Health Department
- C. Hospital/Managed Care Organization
- D. Community Based Organization
- E. Corrections Agency
- F. Other

---

\*\*Note to nurses: CDC is accredited by the American Nurses Credentialing Center's Commission (ANCC) on Accreditation. ANCC credit is accepted by most State Boards of Nursing.

The California Board of Nursing will accept ANCC credit for self-study courses. California nurses should write-in "ANCC - self-study" for this course when applying for re-licensure. A provider number is NOT needed.

The Iowa Board of Nursing will not accept ANCC credit unless nurses seek special post-approval from the Iowa Board of Nursing.

4. Do you provide any services or medical care to hepatitis C patients/clients?
  - A. Yes
  - B. No
  
5. Indicate the approximate % of time that you spend on your job providing services or medical care to hepatitis C patients/clients.
  - A. < 10%
  - B. 10%-25%
  - C. >25%-49%
  - D.  $\geq$  50%
  - E. Not applicable
  
6. The language level was:
  - A. Too basic
  - B. Just right
  - C. Too technical
  
7. The amount of information was:
  - A. Not enough
  - B. Just right
  - C. Too much
  
8. The level of interactivity (i.e., study questions, case studies, links, animations) in this web-based training was:
  - A. Not enough
  - B. Just right
  - C. Too much
  
9. Indicate how you preferred working through the Study Questions.
  - A. Typed the answer on the computer before checking the real answer
  - B. Did not type the answer on the computer before checking the real answer
  - C. Sometimes typed the answer and sometimes did not, before checking the real answer
  - D. Did not work through the Study Questions

# Hepatitis C

Glossary

Acute hepatitis C	Newly acquired symptomatic hepatitis C virus (HCV) infection.
ALT	Alanine aminotransferase.
Anti-HCV	Antibody to HCV that develops in response to HCV infection; detectable in persons with acute, chronic, and resolved infection.
AST	Aspartate aminotransferase.
Chronic (persistent) HCV Infection	Persistent infection with HCV; characterized by detection of HCV RNA $\geq$ 6 months after newly acquired infection.
Chronic hepatitis C	Liver inflammation in patients with chronic HCV infection; characterized by abnormal levels of liver enzymes.
CSTE	Council of State and Territorial Epidemiologists.
DNA	Deoxyribonucleic acid.
EIA	Enzyme immunoassay.
FDA	U.S. Food and Drug Administration.
HBV	Hepatitis B virus.
HCC	Hepatocellular carcinoma.
HCV	Hepatitis C virus.
HCV-positive	Positive for anti-HCV as verified by supplemental testing or positive for HCV RNA.
HCV RNA	Hepatitis C virus ribonucleic acid.
HIV	Human immunodeficiency virus.
IG	Immune globulin.
IM	Intramuscular.
IV	Intravenous
MSM	Men who have sex with men.
NHANES III	Third National Health and Nutrition Examination Survey.
NIH	National Institutes of Health.
Positive predictive value	Probability that a positive screening test is truly positive; dependent on prevalence of disease in a population.
Qualitative RT-PCR for HCV RNA	Test to detect HCV RNA by amplification of viral genetic sequences.
Qualitative assays for HCV RNA	Test to detect HCV RNA concentration (viral load) by amplification of viral genetic sequences or by signal amplification.
Resolved HCV infection	Recovery following hepatitis C virus infection; characterized by sustained disappearance of serum HCV RNA and normalization of liver enzymes.
RIBA™	Recombinant immunoblot assay.
RNA	Ribonucleic acid.
RT-PCR	Reverse transcriptase polymerase chain reaction.
STD	Sexually transmitted disease.
Supplemental anti-HCV test	Additional test (i.e., RIBA™) used to verify a positive anti-HCV result obtained by EIA.

# Hepatitis C

## Introduction & Background

3.9  
million

An estimated 3.9 million Americans have been infected with HCV

Hepatitis C virus (HCV) infection is the most common chronic bloodborne infection in the United States. CDC staff estimate that during the 1980s, an average of 242,000 new infections occurred each year. Since 1989, the annual number of new infections has declined by >80% to 36,000 by 1996. Data from the Third National Health and Nutrition Examination Survey (NHANES III), conducted during 1988–1994, have indicated that an estimated 3.9 million (1.8%) Americans have been infected with HCV. Most of these persons are chronically infected and might not be aware of their infection because they are not clinically ill. Infected persons serve as a source of transmission to others and are at risk for chronic liver disease or other HCV-related chronic diseases during the first two or more decades following initial infection.

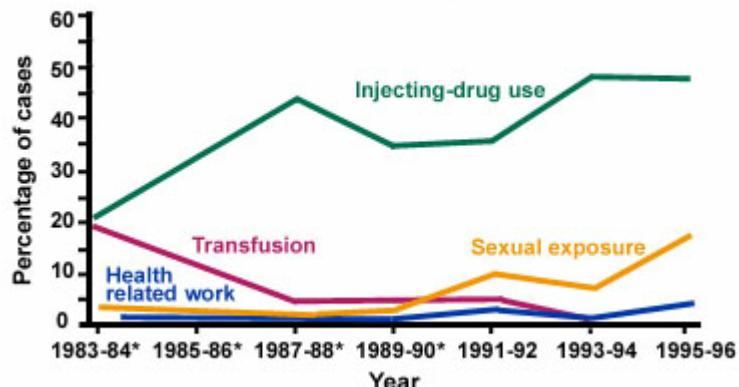

Chronic liver disease is the tenth leading cause of death among adults in the United States, and accounts for approximately 25,000 deaths annually, or approximately 1% of all deaths. Population-based studies indicate that 40% of chronic liver disease is HCV-related, resulting in an estimated 8,000–10,000 deaths each year. Current estimates of medical and work-loss costs of HCV-related acute and chronic liver disease are >\$600 million annually, and HCV- associated end-stage liver disease is the most frequent indication for liver transplantation among adults. Because most HCV-infected persons are aged 30–49 years, the number of deaths attributable to HCV- related chronic liver disease could increase substantially during the next 10–20 years as this group of infected persons reaches ages at which complications from chronic liver disease typically occur.

HCV is transmitted primarily through large or repeated direct percutaneous exposures to blood. In the United States, the relative importance of the two most common exposures associated with transmission of HCV, blood transfusion and injecting-drug use, has changed over time. Blood transfusion, which accounted for a substantial proportion of HCV infections acquired >15 years ago, rarely accounts for recently acquired infections. Since 1994, risk for transfusion-transmitted HCV infection has been so low that CDC's sentinel counties viral hepatitis surveillance system has been unable to detect any transfusion-associated cases of acute hepatitis C, although the risk is not zero. In contrast, injecting-drug use consistently has accounted for a substantial proportion of HCV infections and currently accounts for 60% of HCV transmission in the United States. A high proportion of infections continue to be associated with injecting-drug use, but for reasons that are unclear, the dramatic decline in the incidence of acute hepatitis C since 1989 correlates with a decrease in cases among injecting-drug users.

Reducing the burden of HCV infection and HCV-related disease in the United States requires implementation of primary prevention activities to reduce the risk for contracting HCV infection and secondary prevention activities to reduce the risk for liver and other chronic diseases in HCV-infected persons.

Figure 1

**Figure 1. Reported cases of acute hepatitis C by selected risk factors - United States, 1983-1996**

## BACKGROUND

Prospective studies of transfusion recipients in the United States demonstrated that rates of posttransfusion hepatitis in the 1960s exceeded 20%. In the mid-1970s, available diagnostic tests indicated that 90% of posttransfusion hepatitis was not caused by hepatitis A or hepatitis B viruses and that the move to all-volunteer blood donors had reduced risks for posttransfusion hepatitis to 10%. Although non-A, non-B hepatitis (i.e., neither type A nor type B) was first recognized because of its association with blood transfusion, population-based sentinel surveillance demonstrated that this disease accounted for 15% to 20% of community-acquired viral hepatitis in the United States. Discovery of HCV by molecular cloning in 1988 showed that non-A, non-B hepatitis was primarily caused by HCV infection.

## Epidemiology

### Demographic Characteristics

HCV infection occurs among persons of all ages, but the highest incidence rate of acute hepatitis C is found among persons aged 20 to 39 years, and males predominate. African Americans and whites have similar incidence rates of acute disease; persons of Hispanic ethnicity have higher rates. In the general population, the highest prevalence rates of HCV infection are found among persons aged 30 to 49 years, and among males. Unlike the racial/ethnic pattern of acute disease, African Americans have a substantially higher prevalence of HCV infection than do whites (Figure 2).

## patient perspective

*I would like for people to keep in mind that often we make judgments about a person's likelihood to participate in certain behaviors based on the way we perceive them. For example, how they appear; what kind of job they have; and what kind of lifestyle they live. We then make assumptions about whether they are likely to be at risk for certain things or not. In my case, I think that people were not fearful of me participating in something like injection drug use because I was fairly successful. I had a job and degree and all kinds of stuff-- and therefore they didn't expect me to be doing -- you know, participating in injection drug use.*

## ? ? ? ? ? study question

1.1 What race/ethnic group has the highest prevalence of HCV infection?

- A. White
- B. African American
- C. Hispanic Ethnicity

# Hepatitis C

## Epidemiology

### Prevalence of HCV

The greatest variation in prevalence of HCV infection occurs among persons with different risk factors for infection. The highest prevalence of infection is found among those with large or repeated direct percutaneous exposures to blood (e.g., persons with hemophilia treated with clotting factor concentrates produced before 1987, injecting-drug users, and recipients of transfusions from HCV-positive donors). Moderate prevalence is found among those with frequent but smaller direct percutaneous exposures (e.g., long-term hemodialysis patients). Lower prevalence of HCV-infection is found among those with inapparent percutaneous or mucosal exposures (e.g., health-care workers). Lowest prevalence of HCV infection is found among those with no high-risk characteristics (e.g., volunteer blood donors). The estimated prevalence of persons with different risk factors and characteristics also varies widely in the United States population (Table 1).

### ? ? ? ? ? study question

1.2 What is the prevalence of HCV infection among the general population?

- A. 30 %
- B. < 2%
- C. 2 %

# Hepatitis C

## Epidemiology

## Transmission Modes

### OVERVIEW

Most risk factors associated with transmission of HCV in the United States were identified in case-control studies conducted during 1978-1986. These risk factors included blood transfusion, injecting-drug use, employment in patient care or clinical laboratory work, exposure to a sex partner or household member who has had a history of hepatitis, exposure to multiple sex partners, and low socioeconomic level. These studies reported no association with military service or exposures resulting from medical, surgical, or dental procedures, tattooing, acupuncture, ear piercing, or foreign travel. If transmission from such exposures does occur, the frequency might be too low to detect.

### Transfusions & Transplants

Currently, HCV is rarely transmitted by blood transfusion. During 1985-1990, cases of transfusion-associated non-A, non-B hepatitis declined by >50% because of screening policies that excluded donors with human immunodeficiency virus (HIV) infection and donors with surrogate markers for non-A, non-B hepatitis. By 1990, risk for transfusion-associated HCV infection was approximately 1.5% per recipient or approximately 0.02% per unit transfused. During May 1990, routine testing of donors for evidence of HCV infection was initiated, and during July 1992, more sensitive-multi-antigen- testing was implemented, reducing further the risk for infection to 0.001% per unit transfused ( i.e.,1 in 100,000 per unit transfused).

**Current risk for transfusion-associated hepatitis C  
is 1/100,000 per unit transfused.**

Receipt of clotting factor concentrates prepared from plasma pools posed a high risk for HCV infection until effective procedures to inactivate viruses, including HCV, were introduced during 1985 (Factor VIII) and 1987 (Factor IX). Persons with hemophilia who were treated with products before inactivation of those products have prevalence rates of HCV infection as high as 90%. Although plasma derivatives (e.g., albumin and immune globulin (IG) for intramuscular (IM) administration) have not been associated with transmission of HCV infection in the United States, intravenous (IV) IG that was not virally inactivated was the source of one outbreak of hepatitis C during 1993-1994. Since December 1994, all IG products - IV and IM- commercially available in the United States must undergo an inactivation procedure or be negative for HCV RNA (ribonucleic acid) before release.

Transplantation of organs (e.g., heart, kidney, or liver) from infectious donors to the organ recipient also carried a high risk for transmitting HCV infection before donor screening. Limited studies of

recipients of transplanted tissue have implicated transmission of HCV only from nonirradiated bone tissue of unscreened donors. As with blood donor screening, use of anti-HCV (antibody to hepatitis C virus)- negative organ and tissue donors has virtually eliminated risks for HCV transmission from transplantation.

### **Injection and Other Illegal Drug Use**

Although the number of cases of acute hepatitis C among injecting-drug users has declined dramatically since 1989, both incidence and prevalence of HCV infection remain high in this group. Injecting-drug use currently accounts for most HCV transmission in the United States, and has accounted for a substantial proportion of HCV infections during the past decades. Many persons with chronic HCV infection might have acquired their infection 20 to 30 years ago as a result of limited or occasional illegal drug injecting. Injecting-drug use leads to HCV transmission in a manner similar to that for other blood borne pathogens ( i.e., through transfer of HCV-infected blood by sharing syringes and needles either directly or through contamination of drug preparation equipment). However, HCV infection is acquired more rapidly after initiation of injecting than other viral infections (i.e., hepatitis B virus (HBV) and human immunodeficiency virus (HIV), and rates of HCV infection among young injecting-drug users are four times higher than rates of HIV infection. After 5 years of injecting, as many as 90% of users are infected with HCV. More rapid acquisition of HCV infection compared with other viral infections among injecting-drug users is likely caused by high prevalence of chronic HCV infection among injecting-drug users, which results in a greater likelihood of exposure to an HCV-infected person.

A study conducted among volunteer blood donors in the United States documented that HCV infection has been independently associated with a history of intranasal cocaine use. (The mode of transmission could be through sharing contaminated straws.) Data from NHANES III indicated that 14% of the general population have used cocaine at least once. Although NHANES III data also indicated that cocaine use was associated with HCV infection, injecting-drug use histories were not ascertained. Among patients with acute hepatitis C identified in CDC's sentinel counties viral hepatitis surveillance system since 1991, intranasal cocaine use in the absence of injecting-drug use was uncommon. Thus, at least in the recent past, intranasal cocaine use rarely appears to have contributed to transmission. Until more data are available, whether persons with a history of noninjecting illegal drug use alone (e.g., intranasal cocaine use) are likely to be infected with HCV remains unknown.

**Injecting drug use is the primary risk factor for acquiring HCV infection**

## patient perspective

*I have since learned how high of a likelihood it is for someone participating in injection drug use to become infected with HCV and when I was messing around with injection drug use or heavily into it I hadn't ever really thought about that possibility. I thought I was being careful to not be infected with HIV and I thought I was minimizing my risk, when in fact that wasn't the only thing I should have been worrying about, you know. I ended up HIV negative but living with Hepatitis C which does affect my life.*

### Nosocomial and Occupational Exposures

Nosocomial transmission of HCV is possible if infection-control techniques or disinfection procedures are inadequate and contaminated equipment is shared among patients. Although reports from other countries do document nosocomial HCV transmission, such transmission rarely has been reported in the United States, other than in chronic hemodialysis settings. Prevalence of anti-HCV positivity among chronic hemodialysis patients averages 10%, with some centers reporting rates >60%. Both incidence and prevalence studies have documented an association between anti-HCV positivity and increasing years on dialysis, independent of blood transfusion. These studies, as well as investigations of dialysis-associated outbreaks of hepatitis C, indicate that HCV transmission might occur among patients in a hemodialysis center because of incorrect implementation of infection-control practices, particularly sharing of medication vials and supplies.

Health-care, emergency medical (e.g., emergency medical technicians and para-medics), and public safety workers (e.g., fire-service, law-enforcement, and correctional facility personnel) who have exposure to blood in the workplace are at risk for being infected with bloodborne pathogens. However, prevalence of HCV infection among health-care workers, including orthopedic, general, and oral surgeons, is no greater than the general population, averaging 1%-2%, and is 10 times lower than that for HBV infection. In a single study that evaluated risk factors for infection, a history of unintentional needle-stick injury was the only occupational risk factor independently associated with HCV infection.

HCV prevalence among HCWs is not higher than in the general population.

## **Percutaneous Exposures in Other Settings**

In other countries, HCV infection has been associated with folk medicine practices, tattooing, body piercing, and commercial barbering. However, in the United States, case-control studies have reported no association between HCV infection and these types of exposures. In addition, of patients with acute hepatitis C who were identified in the CDC's sentinel counties viral hepatitis surveillance system during the past 15 years and who denied a history of injecting- drug use, only 1% reported a history of tattooing or ear piercing, and none reported a history of acupuncture. Among injecting-drug users, frequency of tattooing and ear piercing also was uncommon (3%).

Although any percutaneous exposure has the potential for transferring infectious blood and potentially transmitting bloodborne pathogens (i.e., HBV, HCV, or HIV), no data exist in the United States indicating that persons with exposures to tattooing and body piercing alone are at increased risk of HCV infection. Further studies are needed to determine if these types of exposures and settings in which they occur (e.g., correctional institutions, unregulated commercial establishments), are risk factors for HCV infection in the United States.

**No data exist in the U.S. indicating that persons with exposures to tattooing and body piercing alone are at increased risk of HCV infection**

## **Sexual Activity**

Case-control studies have reported an association between exposure to a sex contact with a history of hepatitis or exposure to multiple sex partners and acquiring hepatitis C. In addition, 15%-20% of patients with acute hepatitis C who have been reported to CDC's sentinel counties surveillance system, have a history of sexual exposure in the absence of other risk factors. Two thirds of these have an anti-HCV-positive sex partner, and one third reported >2 partners in the 6 months before illness.

In contrast, a low prevalence of HCV infection has been reported by studies of long-term spouses of patients with chronic HCV infection who had no other risk factors for infection. Five of these studies have been conducted in the United States, involving 30-85 partners each, in which average prevalence of HCV infection was 1.5% (range: 0% to 4.4%). Among partners of persons with hemophilia coinfected with HCV and HIV, two studies have reported an average prevalence of HCV infection of 3%. One additional study evaluated potential transmission of HCV between sexually transmitted disease (STD) clinic patients, who denied percutaneous risk factors, and their steady partners. Prevalence of HCV infection among male patients with an anti-HCV-positive female partner (7%) was no different than that among males with a negative female partner (8%). However, female patients with an anti-HCV-positive partner were almost fourfold more likely to have HCV infection than females with a negative male partner (10% versus 3%, respectively). These data indicate that, similar to other bloodborne viruses, sexual transmission of HCV from males to females might be more efficient

than from females to males.

Among persons with evidence of high-risk sexual practices (e.g., patients attending STD clinics and female prostitutes) who denied a history of injecting-drug use, prevalence of anti-HCV has been found to average 6% (range: 1%-10%). Specific factors associated with anti-HCV positivity for both heterosexuals and men who have sex with men (MSM) included greater numbers of sex partners, a history of prior STDs, and failure to use a condom. However, the number of partners associated with infection risk varied among studies, ranging from >1 partner in the previous month to >50 in the previous year. In studies of other populations, the number of partners associated with HCV infection also varied, ranging from >2 partners in the 6 months before illness for persons with acute hepatitis C, to  $\geq 5$  partners/year for HCV-infected volunteer blood donors, to  $\geq 10$  lifetime partners for HCV- infected persons in the general population.

Only one study has documented an association between HCV infection and MSM activity, and at least in STD clinic settings, the prevalence rate of HCV infection among MSM generally has been similar to that of heterosexuals. Because sexual transmission of bloodborne viruses is recognized to be more efficient among MSM compared with heterosexual men and women, why HCV infection rates are not substantially higher among MSM compared with heterosexuals is unclear. This observation and the low prevalence of HCV infection observed among long-term spouses of persons with chronic HCV infection have raised doubts regarding the importance of sexual activity in transmission of HCV. Unacknowledged percutaneous risk factors (i.e., illegal injecting-drug use) might contribute to increased risk for HCV infection among persons with high-risk sexual practices.

Although considerable inconsistencies exist among studies, data indicate overall that sexual transmission of HCV appears to occur, but that the virus is inefficiently spread through this manner. More data are needed to determine the risk for, and factors related to, transmission of HCV between long-term steady partners as well as among persons with high-risk sexual practices, including whether other STDs promote transmission of HCV by influencing viral load or modifying mucosal barriers.

Sexual transmission of HCV does occur, but is inefficiently spread through this manner

## ? ? ? ? ? study question

1.3 Sexual activity is an inefficient way to transmit HCV.

True

False

## **Household Contact**

Case-control studies also have reported an association between non-sexual household contact and acquiring hepatitis C. The presumed mechanism of transmission is direct or inapparent percutaneous or permucosal exposure to infectious blood or body fluids containing blood. In a recent investigation in the United States, an HCV-infected mother transmitted HCV to her hemophilic child during performance of home infusion therapy, presumably when she had an unintentional needle stick, and subsequently used the contaminated needle in the child.

Although prevalence of HCV infection among nonsexual household contacts of persons with chronic HCV infection in the United States is unknown, HCV transmission to such contacts is probably uncommon. In studies from other countries of nonsexual household contacts of patients with chronic hepatitis C, average anti- HCV prevalence was 4%. Although infected contacts in these studies reported no other commonly recognized risk factors for hepatitis C, most of these studies were done in countries where exposures commonly experienced in the past from contaminated equipment used in traditional and nontraditional medical procedures might have contributed to clustering of HCV infections in families.

**Transmission of HCV within a household is uncommon**

## **Perinatal**

The average rate of HCV infection among infants born to HCV-positive, HIV negative women is 5%-6% (range: 0%-25%), based on detection of anti-HCV and HCV RNA, respectively. The average infection rate for infants born to women co-infected with HCV and HIV is higher - 14% (range: 5%-36%) and 17%, based on detection of anti-HCV and HCV RNA, respectively. The only factor consistently found to be associated with transmission has been the presence of HCV RNA in the mother at the time of birth. Although two studies of infants born to HCV-positive, HIV-negative women reported an association with titer of HCV RNA, each study reported a different level of HCV RNA related to transmission. Studies of HCV/HIV-coinfected women more consistently have indicated an association between virus titer and the transmission of HCV.

**The only consistent factor found to be associated with HCV transmission during birth is the presence of HCV in the mother at the time of birth**

Data regarding the relationship between delivery mode and HCV transmission are limited and presently indicate no difference in infection rates between infants delivered vaginally compared with cesarean-delivered infants. The transmission of HCV infection through breast milk has not been documented. In the studies that have evaluated breastfeeding in infants born to HCV-infected women, the average rate of infection was 4% in both breastfed and bottle-fed infants.

Diagnostic criteria for perinatal HCV infection have not been established. Various anti-HCV patterns have been observed in both infected and uninfected infants of anti-HCV-positive mothers.

Passively acquired maternal antibody might persist for some months, but probably not for >12 months. HCV RNA can be detected as early as 1 to 2 months.

**Breast feeding is not contraindicated  
for HCV-positive mothers**

## **? ? ? ? ? study question**

- 1.4 What is the risk for perinatal transmission of HCV?
- A. < 1 %
  - B. 5 - 6 %
  - C. 25 %

### **Persons With No Recognized Source of Infection**

Recent studies have demonstrated that injecting-drug use currently accounts for 60% of HCV transmission in the United States.

Although the role of sexual activity in the transmission of HCV remains unclear,  $\leq$  20% of persons with HCV infection report sexual exposures (i.e., exposure to an infected sex partner or to multiple partners) in the absence of percutaneous risk factors. Other known exposures (i.e., occupational, hemodialysis, household, perinatal) together account for approximately 10% of infections. Thus, a potential risk factor can be identified for approximately 90% of persons with HCV infection. In the remaining 10%, no recognized source of infection can be identified, although most persons in this category are associated with low socioeconomic level. Although low socioeconomic level has been associated with several infectious diseases and might be a surrogate for high-risk exposures, its nonspecific nature makes targeting prevention measures difficult.

**No recognized source of infection can  
be identified in 10% of cases**

Screening & Diagnostic Tests

Serologic  
Assays

Nucleic Acid (RNA)  
Detection

# Hepatitis C

## Screening & Diagnostic Tests

### Serologic Assays

The only tests currently approved by the Food and Drug Administration (FDA) for diagnosis of HCV infection are those that measure anti-HCV (Table 2). These tests detect anti-HCV in  $\geq 97\%$  of infected patients, but do not distinguish between acute, chronic, or resolved infection. As with any screening test, positive predictive value of the enzyme immunoassay (EIA) for anti-HCV varies depending on the prevalence of infection in the population and is low in populations with an HCV infection prevalence of  $<10\%$ . Supplemental testing with a more specific assay (i.e., recombinant strip immunoblot assay [RIBA<sup>TM</sup>]) of a specimen with a positive EIA result prevents reporting of false-positive results, particularly in settings where asymptomatic persons are being tested.

Supplemental test results may be reported as positive, negative, or indeterminate. An anti-HCV-positive person is defined as one whose serologic results are EIA-test-positive and supplemental-test-positive. Persons with a negative EIA test result or a positive EIA and a negative supplemental test result are considered uninfected, unless other evidence exists to indicate HCV infection (e.g., abnormal ALT levels in immunocompromised persons or persons with no other etiology for their liver disease).

Indeterminate supplemental test results have been observed in the process of seroconversion, as well as in persons chronically infected with HCV. Indeterminate anti-HCV results also might indicate a false-positive result, particularly in those persons at low risk for HCV infection.

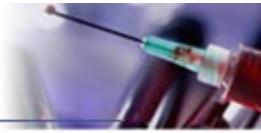

### ? ? ? ? ? study question

2.1 An anti-HCV-positive person is defined as:

- A. one whose serologic results are EIA-positive and RIBA-**negative**.
- B. one whose serologic results are EIA-positive and RIBA-**positive**.

# Hepatitis C

## Screening & Diagnostic Tests

### Nucleic Acid (RNA) Detection

The diagnosis of HCV infection also is possible by qualitatively detecting HCV RNA using gene amplification techniques (e.g., RT-PCR). HCV RNA can be detected in serum or plasma within 1-2 weeks after exposure to the virus and weeks before the onset of ALT elevations or the appearance of anti-HCV. Rarely, detection of HCV RNA might be the only evidence of HCV infection. Although RT-PCR assay kits for HCV RNA are available for research purposes from various manufacturers of diagnostic reagents, none have been approved by FDA. In addition, many laboratories perform RT-PCR using in-house laboratory methods and reagents.

Although not FDA-approved, RT-PCR assays for HCV infection are used commonly in clinical practice. Most RT-PCR assays have a lower limit of detection of 100-1000 viral genome copies per mL. With adequate optimization of RT-PCR assays, 75%-85% of persons who are anti-HCV-positive and > 95% of persons with acute or chronic hepatitis C will test positive for HCV RNA. Some HCV-infected persons might be only intermittently HCV RNA positive, particularly those with acute hepatitis C or with end stage liver disease caused by hepatitis C. To minimize false-negative results, serum must be separated from cellular components within 2-4 hours after collection, and preferably stored frozen at -20°C or -70°C. If shipping is required, frozen samples should be protected from thawing. Because of assay variability, rigorous quality assurance and control should be in place in clinical laboratories performing this assay, and proficiency testing is recommended.

Quantitative assays for measuring the concentration (titer) of HCV RNA have been developed and are available from commercial laboratories, including a quantitative RT-PCR (Amplicor HCV Monitor™, Roche Molecular Systems, Branchburg, New Jersey) and a branched DNA (deoxyribonucleic acid) signal amplification assay (Quantiplex™ HCV RNA Assay [bDNA], Chiron Corp., Emeryville, California) (Table 2). These assays also are not FDA-approved, and compared with qualitative RT-PCR assays, are less sensitive with lower limits of detection of 500 viral genome copies per mL for the Amplicor HCV Monitor™ to 200,000 genome equivalents per mL for the Quantiplex™ HCV RNA Assay. In addition, they each use a different standard, which precludes direct comparisons between the two assays. Quantitative assays should not be used as a primary test to confirm or exclude the diagnosis of HCV infection or to monitor the endpoint of treatment. Patients with chronic hepatitis C generally circulate virus at levels of  $10^5$  to  $10^7$  genome copies per mL. Testing for the level of HCV RNA might

help predict likelihood of response to antiviral therapy, although sequential measurement of HCV RNA levels has not proven useful in managing patients with hepatitis C.

At least six different genotypes and > 90 subtypes of HCV exist. Approximately 70% of HCV-infected persons in the United States are infected with genotype 1, with frequency of subtype 1a predominating over subtype 1b. Different nucleic acid detection methods are available commercially to group isolates of HCV, based on genotypes and subtypes. Evidence is limited regarding differences in clinical features, disease outcome, or progression to cirrhosis or hepatocellular carcinoma (HCC) among persons with different genotypes. However, differences do exist in responses to antiviral therapy according to HCV genotype. Rates of response in patients infected with genotype 1 are substantially lower than in patients with other genotypes. Patients with genotype 1 may require a longer period of treatment. Thus, genotyping might be warranted among persons with chronic hepatitis C who are being considered for antiviral therapy.

## ? ? ? ? ? study question

2.2 Patients infected with HCV genotype 1 have higher response rates to antiviral therapy than patients infected with other genotypes.

True

False

# Hepatitis C

Clinical Features & Natural History

**Acute HCV  
Infection**

**Chronic HCV  
Infection**

# Hepatitis C

## Clinical Features & Natural History

### Acute HCV Infection

Persons with acute HCV infection typically are either asymptomatic or have a mild clinical illness; 60%-70% have no discernible symptoms; 20%-30% might have jaundice; and 10%-20% might have non-specific symptoms (e.g., anorexia, malaise, or abdominal pain). Clinical illness in patients with acute hepatitis C who seek medical care is similar to that of other types of viral hepatitis, and serologic testing is necessary to determine the etiology of hepatitis in an individual patient. In  $\leq 20\%$  of these patients, onset of symptoms might precede anti-HCV seroconversion. Average time period from exposure to symptom onset is 6-7 weeks, whereas average time period from exposure to seroconversion is 8-9 weeks. Anti-HCV can be detected in 80% of patients within 15 weeks after exposure, in  $\geq 90\%$  within 5 months after exposure, and in  $\geq 97\%$  by 6 months after exposure. Rarely, seroconversion might be delayed until 9 months after exposure.

The course of acute hepatitis C is variable, although elevations in serum ALT levels, often in a fluctuating pattern, are its most characteristic feature. Normalization of ALT levels might occur and suggests full recovery, but this is frequently followed by ALT elevations that indicate progression to chronic disease. Fulminant hepatic failure following acute hepatitis C is rare.

#### ? ? ? ? ? study question

3.1 With acute HCV infection, the average time from exposure to onset of symptoms is:

- A. 4-5 weeks
- B. 6-7 weeks
- C. 8-9 weeks

# Hepatitis C

## Clinical Features & Natural History

### Chronic HCV Infection

After acute infection, 15%-25% of persons appear to resolve their infection without sequelae as defined by the sustained absence of HCV RNA in serum and normalization of ALT levels. Chronic HCV infection develops in most persons (75%-85%) with persistent or fluctuating ALT elevations indicating active liver disease developing in 60%-70% of chronically infected persons. In the remaining 30%-40% of chronically infected persons, ALT levels are normal. No clinical or epidemiologic features among patients with acute infection have been found to be predictive of either persistent infection or chronic liver disease. Moreover, various ALT patterns have been observed in these patients during follow-up, and patients might have prolonged periods ( $\geq 12$  months) of normal ALT activity even though they have histologic-confirmed chronic hepatitis. Thus, a single ALT determination cannot be used to exclude ongoing hepatic injury, and long-term follow-up of patients with HCV infection is required to determine their clinical outcome or prognosis.

The course of chronic liver disease is usually insidious, progressing at a slow rate without symptoms or physical signs in the majority of patients during the first two or more decades after infection. Frequently, chronic hepatitis C is not recognized until asymptomatic individuals are identified as HCV-positive during blood donor screening, or elevated ALT levels are detected during routine physical examinations. Most studies have reported that cirrhosis develops in 10%-20% of persons with chronic hepatitis C over a period of 20-30 years, and HCC in 1%-5%, with striking geographic variations in rates of this disease. However, when cirrhosis is established, the rate of development of HCC might be as high as 1%-4% per year. In contrast, a study of  $> 200$  women 17 years after they received HCV-contaminated RH factor IG reported that only 2.4% had evidence of cirrhosis and none had died. Thus, longer term follow-up studies are needed to assess the lifetime consequences of chronic hepatitis C, particularly among those who acquired their infection at young ages.

Although factors predicting severity of liver disease have not been well defined, recent data indicate that increased alcohol intake, being aged  $> 40$  years at infection, and being male are associated with more severe liver disease. In particular, among persons with alcoholic liver disease and HCV infection, liver disease progresses more rapidly; among those with cirrhosis, a higher risk for development of HCC exists. Furthermore, even intake of moderate amounts ( $> 10$  grams/day) of alcohol in patients with chronic hepatitis C might enhance disease progression. More severe liver injury observed in persons with alcoholic liver disease and HCV

**TABLE 2. Tests for hepatitis C virus (HCV) infection**

Test/Type	Application	Comments
<b>Hepatitis C virus antibody (anti-HCV)</b>		
• EIA (enzyme immunoassay) • Supplemental assay (i.e., recombinant immunoblot assay [RIBA™])	• Indicates past or present infection, but does not differentiate between acute, chronic, or resolved infection • All positive EIA results should be verified with a supplemental assay	• Sensitivity ≥97% • EIA alone has low-positive predictive value in low-prevalence populations
<b>HCV RNA (hepatitis C virus ribonucleic acid)</b>		
<b>Qualitative tests*†</b>		
• Reverse transcriptase polymerase chain reaction (RT-PCR) amplification of HCV RNA by in-house or commercial assays (e.g., Amplicor HCV™)	• Detect presence of circulating HCV RNA • Monitor patients on antiviral therapy	• Detect virus as early as 1–2 weeks after exposure • Detection of HCV RNA during course of infection might be intermittent; a single negative RT-PCR is not conclusive • False-positive and false-negative results might occur
<b>Quantitative tests*†</b>		
• RT-PCR amplification of HCV RNA by in-house or commercial assays (e.g., Amplicor HCV Monitor™) • Branched chain DNA§ (bDNA) assays (e.g., Quantiplex™ HCV RNA Assay)	• Determine concentration of HCV RNA • Might be useful for assessing the likelihood of response to antiviral therapy	• Less sensitive than qualitative RT-PCR • Should not be used to exclude the diagnosis of HCV infection or to determine treatment endpoint
<b>Genotype*†</b>		
• Several methodologies available (e.g., hybridization, sequencing)	• Group isolates of HCV based on genetic differences, into 6 genotypes and >90 subtypes • With new therapies, length of treatment might vary based on genotype	• Genotype 1 (subtypes 1a and 1b) most common in United States and associated with lower response to antiviral therapy
<b>Serotype*</b>		
• EIA based on immunoreactivity to synthetic peptides (e.g., Murex HCV Serotyping 1–6 Assay)	• No clinical utility	• Cannot distinguish between subtypes • Dual infections often observed

\* Currently not U.S. Food and Drug Administration approved; lack standardization.

† Samples require special handling (e.g., serum must be separated within 2–4 hours of collection and stored frozen [-20 C or -70 C]; frozen samples should be shipped on dry ice).

§ Deoxyribonucleic acid.

infection possibly is attributable to alcohol-induced enhancement of viral replication or increased susceptibility of cells to viral injury. In addition, persons who have chronic liver disease are at increased risk for fulminant hepatitis A.

Extrahepatic manifestations of chronic HCV infection are considered to be of immunologic origin, and include cryoglobulinemia, membranoproliferative glomerulonephritis, and porphyria cutanea tarda. Other extrahepatic conditions have been reported, but definitive associations of these conditions with HCV infection have not been established. These include seronegative arthritis, Sjögren syndrome, autoimmune thyroiditis, lichen planus, Mooren corneal ulcers, idiopathic pulmonary fibrosis (Hamman-Rich syndrome), polyarteritis nodosa, aplastic anemia, and B-cell lymphomas.

## patient perspective

*To minimize the disease is not a good way to go. I feel like in my case when I was diagnosed diagnosed that it was really minimized, it was given to me in a way such as, yes it's chronic but you really shouldn't be affected that much by-you know, it shouldn't be that big a deal in your life.*

## ? ? ? ? ? study question

3.2 The most characteristic feature of acute hepatitis C is:

- A. stable serum ALT levels
- B. fluctuating serum ALT levels

# Hepatitis C

## Clinical Management & Treatment

HCV-positive patients should be evaluated for the presence and severity of chronic liver disease.

HCV-positive patients should be evaluated for the presence and severity of chronic liver disease. Initial evaluation for presence of disease should include multiple measurements of ALT at regular intervals, because ALT activity fluctuates in persons with chronic hepatitis C. Patients with chronic hepatitis C should be evaluated for the severity of their liver disease and for possible treatment.

Antiviral therapy is recommended for patients with chronic hepatitis C who are at greatest risk for progression to cirrhosis. These persons include anti-HCV-positive patients with persistently elevated ALT levels, detectable HCV RNA, and a liver biopsy that indicates either portal or bridging fibrosis or at least moderate degrees of inflammation and necrosis.

In patients with less severe histologic changes, indications for treatment are less clear, and careful clinical follow-up might be an acceptable alternative to treatment with antiviral therapy (e.g., interferon) because progression to cirrhosis is likely to be slow, if it occurs at all. Similarly, patients with compensated cirrhosis (without jaundice, ascites, variceal hemorrhage, or encephalopathy) might not benefit from interferon therapy. Careful assessment should be made, and the risks and benefits of therapy should be thoroughly discussed with the patient.

Patients with persistently normal ALT values should not be treated outside of clinical trials, as treatment might actually induce liver enzyme abnormalities. Patients with advanced cirrhosis who might be at risk for decompensation with therapy and pregnant women also should not be treated. Interferon treatment is not FDA-approved for patients aged  $<18$  years or  $>60$  years. Treatment of patients who are drinking excessive amounts of alcohol or who are injecting illegal drugs should be delayed until these behaviors have been discontinued for  $\geq 6$  months. Contraindications to treatment with interferon include major depressive illness, cytopenias, hyperthyroidism, renal transplantation, and evidence of autoimmune disease.

Most clinical trials of treatment for chronic hepatitis C have been conducted using alpha interferon. When the recommended regimen of 3 million units administered subcutaneously 3 times/week for 12 months is used, approximately 50% of treated patients have normalization of serum ALT activity (biochemical response), and 33% have a loss of detectable HCV RNA in serum (virologic response) at the end of therapy. However,  $\geq 50\%$  of these patients relapse when therapy is stopped. Thus, 15%-25% have a sustained response as measured by testing for ALT and HCV RNA  $\geq 1$  years after therapy is stopped, many of whom also have histologic improvement. For patients who do not respond by the end of

therapy, retreatment with a standard dose of interferon is rarely effective. Patients who have persistently abnormal ALT levels and detectable HCV RNA in serum after 3 months of interferon are unlikely to respond to treatment, and interferon treatment should be discontinued. These persons might be considered for participation in clinical trials of alternative treatments.

Decreased interferon response rates (<15%) have been found in patients with higher serum HCV RNA titers and HCV genotype 1 (the most common strain of HCV in the United States); however, treatment should not be withheld based solely on these findings.

Therapy for hepatitis C is a rapidly changing area of clinical practice. Combination therapy with interferon and ribavirin, a nucleoside analogue, is approved for the naive treatment of patients with chronic hepatitis C. Studies of patients treated with a combination of ribavirin and interferon have demonstrated a substantial increase in sustained response rates, reaching 40%-50%, compared with response rates of 15%-25% with interferon alone. However, as with interferon alone, combination therapy in patients with genotype 1 is not as successful, and sustained response rates among these patients are still <30%.

Most patients receiving interferon experience flu-like symptoms early in treatment, but these symptoms diminish with continued treatment. Later side effects include fatigue, bone marrow suppression, and neuropsychiatric effects (e.g., apathy, cognitive changes, irritability, and depression). Interferon dosage must be reduced in 10%-40% of patients and discontinued in 5%-15% because of severe side effects. Ribavirin can induce hemolytic anemia and can be problematic for patients with pre-existing anemia, bone marrow suppression, or renal failure. In these patients, combination therapy should be avoided or attempts should be made to correct the anemia. Hemolytic anemia caused by ribavirin also can be life-threatening for patients with ischemic heart disease or cerebral vascular disease. Ribavirin is teratogenic, and female patients should avoid becoming pregnant during therapy.

Other treatments, including corticosteroids, ursodiol, and thymosin, have not been effective. High iron levels in the liver might reduce the efficacy of interferon. Use of iron reduction therapy (phlebotomy or chelation) in combination with interferon has been studied, but results have been inconclusive. Because patients are becoming more interested in alternative therapies (e.g., traditional Chinese medicine, antioxidants, naturopathy, and homeopathy), physicians should be prepared to address questions regarding these topics.

## ? ? ? ? ? study question

4.1 There are no contraindications to HCV treatment with interferon.

True

False

# Hepatitis C

## Post-Exposure

### Immune globulin is not effective for postexposure.

Available data regarding the prevention of HCV infection with IG indicate that IG is not effective for postexposure prophylaxis of hepatitis C. No assessments have been made of postexposure use of antiviral agents (e.g., interferon) to prevent HCV infection. Mechanisms of the effect of interferon in treating patients with hepatitis C are poorly understood, and an established infection might need to be present for interferon to be an effective treatment.

The immediate postexposure setting provides opportunity to identify persons early in the course of their HCV infection. Studies indicate that interferon treatment begun early in the course of HCV infection is associated with a higher rate of resolved infection. However, no data exist indicating that treatment begun during the acute phase of infection is more effective than treatment begun early during the course of chronic HCV infection. In addition, as stated previously, interferon is not FDA-approved for this indication. Determination of whether treatment of HCV infection is more beneficial in the acute phase than in the early chronic phase will require evaluation with well-designed research protocols.

### ? ? ? ? ? study question

5.1 Individuals exposed to HCV should receive IG to prevent infection.

False

# Hepatitis C

## Prevention & Control Recommendations

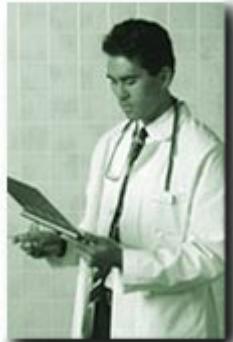

Rationale

Primary  
Prevention  
Recommendations

Secondary  
Prevention  
Recommendations

Testing  
Recommendations

# Hepatitis C

## Prevention & Control Recommendations

### Rationale

Reducing the burden of HCV infection and HCV-related disease in the United States requires implementation of *primary* prevention activities that reduce risks for contracting HCV infection and *secondary* prevention activities that reduce risks for liver and other chronic diseases in HCV-infected persons. In addition, surveillance and evaluation activities are required to determine the effectiveness of prevention programs in reducing the incidence of disease, identifying persons infected with HCV, providing appropriate medical follow-up, and promoting healthy lifestyles and behaviors.

Primary prevention activities can reduce or eliminate potential risk for HCV transmission from a) blood, blood components, and plasma derivatives; b) such high-risk activities as injecting-drug use and sex with multiple partners; and c) percutaneous exposures to blood in health care and other (i.e., tattooing and body piercing) settings. Immunization is not available; therefore, identifying persons at risk but not infected with HCV provides opportunity for counseling on how to reduce their risk for becoming infected.

Secondary prevention activities can reduce risks of chronic disease by identifying HCV-infected persons through diagnostic testing and by providing appropriate medical management and antiviral therapy. Because of the number of persons with chronic HCV infection, identification of these persons must be a major focus of current prevention programs. Identification of persons at risk for HCV infection provides opportunity for testing to determine their infection status, medical evaluation to determine their disease status if infected, and antiviral therapy if appropriate. Identification also provides infected persons opportunity to obtain information concerning how they can prevent further harm to their liver and prevent transmitting HCV to others.

Factors for consideration when making decisions regarding development and implementation of preventive services for a particular disease include the public health importance of the disease, the availability of appropriate diagnostic tests, and the effectiveness of available preventive and therapeutic interventions. However, identification of persons at risk for HCV infection must take into account not only the benefits but also the limitations and drawbacks associated with such efforts. Hepatitis C is a disease of major public health importance, and suitable and accurate diagnostic tests as well as behavioral and therapeutic interventions are available.

Counseling and testing can prevent disease transmission and progression through reducing high-risk practices (e.g., injecting-drug use and alcohol intake). However, the degree to which persons will change their high-risk practices based on

knowing their test results is not known, and possible adverse consequences of testing exist, including disclosure of test results to others that might result in disrupted personal relationships and possible discriminatory action (e.g., loss of employment, insurance, and educational opportunities). Antiviral treatment is also available, and treatment guidelines have been developed. Such treatment is beneficial for many patients, although sustained response rates and mode of delivery are currently less than ideal.

Persons at risk for HCV infection who receive health-care services in the public and private sectors should have access to counseling and testing. Facilities that provide counseling and testing should include services or referrals for medical evaluation and management of persons identified as infected with HCV. Priorities for implementing new counseling and testing programs should be based on providing access to persons who are most likely to be infected or who practice high-risk behaviors.

#### **Elements of a comprehensive strategy to prevent and control hepatitis C virus (HCV) infection and HCV-related disease**

- Primary prevention activities include:
  - screening and testing of blood, plasma, organ, tissue, and semen donors;
  - virus inactivation of plasma-derived products;
  - risk-reduction counseling and services; and
  - implementation and maintenance of infection-control practices.
- Secondary prevention activities include:
  - identification, counseling, and testing of persons at risk, and
  - medical management of infected persons.
- Professional and public education.
- Surveillance and research to monitor disease trends and the effectiveness of prevention activities and to develop improved prevention methods.

## ? ? ? ? ? study question

- 6.1 To reduce the burden of HCV infection and HCV-related disease in the U.S. we only need to implement primary prevention activities such as identifying and educating individuals at high risk.

True

False

# Hepatitis C

## Prevention & Control Recommendations

### Primary Prevention Recommendation

#### Blood, Plasma Derivatives, Organs, Tissues, and Semen

Current practices that exclude blood, plasma, organ, tissue, or semen donors determined to be at increased risk for HCV by history or who have serologic markers for HCV infection must be maintained to prevent HCV transmission from transfusions and transplants. Viral inactivation of clotting factor concentrates and other products derived from human plasma, including IgG products, also must be continued, and all plasma-derived products that do not undergo viral inactivation should be HCV RNA negative by RT-PCR before release.

#### High-Risk Drug and Sexual Practices

Health-care professionals in all patient care settings routinely should obtain a history that inquires about use of illegal drugs (injecting and noninjecting) and evidence of high-risk sexual practices (e.g., multiple sex partners or a history of sexually transmitted disease [STD]). Primary prevention of illegal drug injecting will eliminate the greatest risk factor for HCV infection in the United States. Although consistent data are lacking regarding the extent to which sexual activity contributes to HCV transmission, persons having multiple sex partners are at risk for STDs (e.g., AIDS, hepatitis B, syphilis, gonorrhea, and chlamydia). Counseling and education to prevent initiation of drug-injecting or high-risk sexual practices are important, especially for adolescents. Persons who inject drugs or who are at risk for STDs should be counseled regarding what they can do to minimize their risk for becoming infected or of transmitting infectious agents to others, including need for vaccination against hepatitis B. Injecting and noninjecting illegal drug users and sexually active men who have sex with men (MSM) also should be vaccinated against hepatitis A.

## Prevention messages for persons with high-risk drug or sexual practices

### Persons who use or inject illegal drugs should be advised:

- to stop using and injecting drugs.
- to enter and complete substance abuse treatment, including relapse prevention programs.
- if continuing to inject drugs,
  - to never reuse or "share" syringes, needles, water, or drug preparation equipment; if injection equipment has been used by other persons, first clean the equipment with bleach and water;
  - to use only syringes obtained from a reliable source (e.g., pharmacies);
  - to use a new sterile syringe to prepare and inject drugs; if possible, use sterile water to prepare drugs; otherwise use clean water from a reliable source (such as fresh tap water).
  - to use a new or disinfected container ("cooker") and a new filter ("cotton") to prepare drugs;
  - to clean the injection site prior to injection with a new alcohol swab; and
  - to safely dispose of syringes after one use
- to get vaccinated against hepatitis B and hepatitis A.

### Persons who are at risk for STDs should be advised:

- that the surest way to prevent the spread of HIV infection and other STDs is to have sex with only one uninfected partner or not to have sex at all.
- To use latex condoms correctly and every time to protect themselves and their partners from diseases spread through sexual activity.
- To get vaccinated against hepatitis B, and if appropriate, hepatitis A.

Counseling of persons with potential or existing illegal drug use or high-risk sexual practices should be conducted in the setting in which the patient is identified. If counseling services cannot be provided on-site, patients should be referred to a convenient community resource, or at a minimum, provided easy-to-understand health-education material. STD and drug-treatment clinics, correctional institutions, and HIV counseling and testing sites should routinely provide information

concerning prevention of HCV and HBV infection in their counseling messages. Based on the findings of multiple studies, syringe and needle-exchange programs can be an effective part of a comprehensive strategy to reduce the incidence of bloodborne virus transmission and do not encourage the use of illegal drugs. Therefore, to reduce the risk for HCV infection among injecting- drug users, local communities can consider implementing syringe and needle-exchange programs.

## **PERCUTANEOUS EXPOSURES TO BLOOD IN HEALTH-CARE AND OTHER SETTINGS**

### ***Health-Care Settings***

Health-care, emergency medical, and public safety workers should be educated regarding risk for and prevention of bloodborne infections, including the need to be vaccinated against hepatitis B. Standard barrier precautions and engineering controls should be implemented to prevent exposure to blood. Protocols should be in place for the reporting and follow-up of percutaneous or permucosal exposures to blood or body fluids that contain blood.

Health-care professionals responsible for overseeing patients receiving home infusion-therapy should ensure that patients and their families (or caregivers) are informed of potential risk for infection with bloodborne pathogens, and should assess their ability to use adequate infection-control practices consistently. Patients and families should receive training with a standardized curriculum that includes appropriate infection-control procedures, and these procedures should be evaluated regularly through home visits.

Currently, no recommendations exist to restrict professional activities of health-care workers with HCV infection. As recommended for all health-care workers, those who are HCV-positive should follow strict aseptic technique and standard precautions, including appropriate use of hand washing, protective barriers, and care in the use and disposal of needles and other sharp instruments.

In chronic hemodialysis settings, intensive efforts must be made to educate new staff and reeducate existing staff regarding hemodialysis-specific infection-control practices that prevent the transmission of HCV and other bloodborne pathogens. Hemodialysis center precautions are more stringent than standard precautions. Standard precautions require use of gloves only when touching blood, body fluids, secretions, excretions, or contaminated items. In contrast, hemodialysis-center precautions require glove use whenever patients or hemodialysis equipment is touched. Standard precautions do not restrict use of supplies, instruments, and medications to a single patient; hemodialysis-center precautions specify that none of these items be shared among any patients. Thus, appropriate use of hemodialysis-center precautions should prevent transmission of HCV among chronic hemodialysis patients, and isolation of HCV-positive patients is not necessary or recommended.

### Routine precautions for the care of all hemodialysis patients

- Patients should have specific dialysis stations assigned to them, and chairs and beds should be cleaned after each use.
- Sharing among patients of ancillary supplies such as trays, blood pressure cuffs, clamps, scissors, and other nondisposable items should be avoided.
- Nondisposable items should be cleaned or disinfected appropriately between uses.
- Medications and supplies should not be shared among patients, and medication carts should not be used.
- Medications should be prepared and distributed from a centralized area.
- Clean and contaminated areas should be separated; (e.g., handling and storage of medications and hand washing should not be done in the same or an adjacent area to that where used equipment or blood samples are handled).

### *Other Settings*

Persons who are considering tattooing or body piercing should be informed of potential risks of acquiring infection with bloodborne and other pathogens through these procedures. These procedures might be a source of infection if equipment is not sterile or if the artist or piercer does not follow other proper infection-control procedures (e.g., washing hands, using latex gloves, and cleaning and disinfecting surfaces).

### *patient perspective*

*I continued to drink. I didn't drink real heavily but even the fact that I was drinking at all--alcohol use is not a good idea for people who have Hepatitis C infection and also I had been infected with Hepatitis C through injection drug use so I am presenting to this health care provider with the substance abuse issue. It's very easy for people with substance abuse issues to transfer addiction from one substance to another.*

## ? ? ? ? ? study question

6.2 Primary prevention of illegal injection drug use will eliminate:

- A. the greatest risk factor for HCV in the U.S.
- B. the second greatest risk factor for HCV in the U.S.
- C. the least greatest risk factor for HCV in the U.S.

# Hepatitis C

Prevention & Control Recommendations

## Secondary Prevention Recommendation

### Persons for Whom Routine HCV Testing is Recommended

Testing should be offered routinely to persons most likely to be infected with HCV who might require medical management, and testing should be accompanied by appropriate counseling and medical follow-up. In addition, anyone who wishes to know or is concerned regarding their HCV-infection status should be provided the opportunity for counseling, testing, and appropriate follow-up. The determination of which persons at risk to recommend for routine testing is based on various considerations, including a known epidemiologic relationship between a risk factor and acquiring HCV infection, prevalence of risk behavior or characteristic in the population, prevalence of infection among those with a risk behavior or characteristic, and the need for persons with a recognized exposure to be evaluated for infection.

As part of a complete medical history for all patients, it is important to obtain a history of high risk exposures associated with HCV and other bloodborne pathogens. Such a history can be used to identify asymptomatic persons who should be offered testing for HCV infection. Routine testing is currently recommended only for persons who belong to groups with a known high prevalence of infection.

### **Persons who should be tested routinely for hepatitis C virus (HCV) infection based on their risk for infection**

- Persons who ever injected illegal drugs, including those who experimented once or a few times many years ago and do not self-identify as drug users.
- Persons with selected medical conditions, including:
  - Persons who received clotting factor concentrates produced before 1987.
  - Persons who were ever on chronic (long-term) hemodialysis.
  - Persons with persistently abnormal ALT levels.
- Prior recipients of transfusions or organ transplants, including:
  - Persons who were notified that they received blood from a donor who later tested positive for HCV infection.
  - Persons who received a transfusion of blood or blood components before July 1992.
  - Persons who received an organ transplant before July 1992.

### **Persons who should be routinely tested for HCV infection based on a recognized exposure include:**

- Health-care, emergency medical, and public safety workers after needlesticks, sharps, or mucosal exposures to HCV-positive blood.
- Children born to HCV-positive women.

### ***Persons Who Have Ever Injected Illegal Drugs***

Health-care professionals in primary-care and other appropriate settings routinely should question patients regarding their history of injecting-drug use, and should counsel, test, and evaluate for HCV infection, persons with such histories. Current injecting-drug users frequently are not seen in the primary health-care setting and might not be reached by traditional media; therefore, community-based organizations serving these populations should determine the most effective means of integrating appropriate HCV information and services into their programs.

Testing persons in settings with potentially high proportions of injecting-drug users (e.g., correctional institutions, HIV counseling and testing sites, or drug and STD treatment programs) might be particularly efficient for identifying HCV-positive persons. HCV testing programs in these settings should include counseling and referral or arrangements for medical management. However, limited experience exists in combining HCV programs with existing HIV, STD, or other established services for populations at high risk for infection with

bloodborne pathogens. Persons at risk for HCV infection through limited or occasional drug use, particularly in the remote past, might not be receptive to receiving services in such settings as HIV counseling and testing sites and drug and STD treatment programs. In addition, whether a substantial proportion of this group at risk can be identified in these settings is unknown. Studies are needed to determine the best approaches for reaching persons who might not identify themselves as being at risk for HCV infection.

### ***Persons with Selected Medical Conditions***

Persons with hemophilia who received clotting factor concentrates produced before 1987 and long-term hemodialysis patients should be tested for HCV infection. Educational efforts directed to health-care professionals, patient organizations, and agencies who care for these patients should emphasize the need for these patients to know whether they are infected with HCV and encourage testing for those who have not been tested previously. Periodic testing of long-term hemodialysis patients for purposes of infection control is currently not recommended. However, issues surrounding prevention of HCV and other bloodborne pathogen transmission in long-term hemodialysis settings are currently undergoing discussion, and updating recommendations for this setting is under development.

Persons with persistently abnormal ALT levels are often identified in medical settings. As part of their medical work-up, health-care professionals should test routinely for HCV infection persons with ALT levels above the upper limit of normal on at least two occasions. Persons with other evidence of liver disease identified by abnormal serum aspartate aminotransferase (AST) levels, which is common among persons with alcohol-related liver disease, should be tested also.

### ***Prior Recipients of Blood Transfusions or Organ Transplants***

Persons who might have become infected with HCV through transfusion of blood and blood components should be notified. Two types of approaches should be used — a) a targeted, or directed, approach to identify prior transfusion recipients from donors who tested anti-HCV positive after multiantigen screening tests were widely implemented (July 1992 and later); and b) a general approach to identify all persons who received transfusions before July 1992. A targeted notification approach focuses on a specific group known to be at risk, and will reach persons who might be unaware they were transfused. However, because blood and blood-component donor testing for anti-HCV before July 1992 did not include confirmatory testing, most of these notifications would be based on donors who were not infected with HCV because their test results were falsely positive. A general education campaign to identify persons transfused before July 1992 has the advantage of not being dependent on donor testing status or availability of records, and potentially reaches persons who received HCV-infected blood from donors who tested falsely negative on the less sensitive serologic test, as well as from donors before testing was available.

■ **Persons who received blood from a donor who tested positive for HCV infection after multiantigen screening tests were widely implemented.**

Persons who received blood or blood components from donors who subsequently tested positive for anti-HCV using a licensed multiantigen assay should be notified as provided for in guidance issued by FDA. For specific details regarding this notification, readers should refer to the FDA document, *Guidance for Industry. Current Good Manufacturing Practice for Blood and Blood Components: (1) Quarantine and Disposition of Units from Prior Collections from Donors with Repeatedly Reactive Screening Tests for Antibody to Hepatitis C Virus (Anti-HCV); (2) Supplemental Testing, and the Notification of Consignees and Blood Recipients of Donor Test Results for Anti-HCV. (This document is available on the Internet at* <http://www.fda.gov/cber/gdlns/gmphcv.txt>)

Blood-collection establishments and transfusion services should work with local and state health agencies to coordinate this notification effort. Health-care professionals should have information regarding the notification process and HCV infection so that they are prepared to discuss with their patients why they were notified and to provide appropriate counseling, testing, and medical evaluation. Health-education material sent to recipients should be easy to understand and include information concerning where they can be tested, what hepatitis C means in terms of their day-to-day living, and where they can obtain more information.

■ **Persons who received a transfusion of blood or blood components (including platelets, red cells, washed cells, and fresh frozen plasma) or a solid-organ transplant (e.g., heart, lung, kidney, or liver) before July 1992.**

Patients with a history of blood transfusion or solid-organ transplantation before July 1992 should be counseled, tested, and evaluated for HCV infection. Health-care professionals in primary-care and other appropriate settings routinely should ascertain their patients' transfusion and transplant histories either through questioning their patients, including such risk factors for transfusion as hematologic disorders, major surgery, trauma, or premature birth, or through review of their medical records. In addition, transfusion services, public health agencies, and professional organizations should provide to the public, information concerning the need for HCV testing in this population. Health-care professionals should be prepared to discuss these issues with their patients and provide appropriate counseling, testing, and medical evaluation.

### ***Health-Care, Emergency Medical, and Public Safety Workers After Needle Sticks, Sharps, or Mucosal Exposures to HCV-Positive Blood***

Individual institutions should establish policies and procedures for HCV testing of persons after percutaneous or permucosal exposures to blood and ensure that all personnel are familiar with these policies and procedures. Health-care professionals who provide care to persons exposed to HCV in the occupational setting should be knowledgeable regarding the risk for HCV infection and appropriate counseling, testing, and medical follow-up. IG and antiviral agents are not recommended for postexposure prophylaxis of hepatitis C. Limited data indicate that antiviral therapy might be beneficial when started early in the course of HCV infection, but no guidelines exist for administration of therapy during the acute phase of infection. When HCV infection is identified early, the individual should be referred for medical management to a specialist knowledgeable in this area.

### ***Children Born to HCV-Positive Women***

Because of their recognized exposure, children born to HCV-positive women should be tested for HCV infection. IG and antiviral agents are not recommended for postexposure prophylaxis of infants born to HCV-positive women. Testing of infants for anti-HCV should be performed no sooner than age 12 months, when passively transferred maternal anti-HCV declines below detectable levels. If earlier diagnosis of HCV infection is desired, RT-PCR for HCV RNA may be performed on or after the infant's first well-child visit at age 1–2 months. Umbilical cord blood should not be used for diagnosis of perinatal HCV infection because cord blood can be contaminated by maternal blood. If positive for either anti-HCV or HCV RNA, children should be evaluated for the presence or development of liver disease, and those children with persistently elevated ALT levels should be referred to a specialist for medical management.

### **Postexposure follow-up of health-care, emergency medical, and public safety workers for hepatitis C virus (HCV) infection**

- For the source, baseline testing for anti-HCV.
- For the person exposed to an HCV-positive source, baseline and follow-up testing including
  - baseline testing for anti-HCV and ALT activity; and
  - follow-up testing for anti-HCV (e.g., at 4–6 months) and ALT activity. (If earlier diagnosis of HCV infection is desired, testing for HCV RNA may be performed at 4–6 weeks.)
- Confirmation by supplemental anti-HCV testing of all anti-HCV results reported as positive by enzyme immunoassay.

### **patient perspective**

***Now that I have been diagnosed for a couple of years, my current physician does some things that I really like. First off, he continues to remind me to take care of myself, to eat well, etc. He continues to remind me that there is a message of hope and sometimes I become discouraged so I'm glad that he does that. Also, he is able to help me plan life issues such as whether or not it's OK to marry and have children***

### **? ? ? ? ? study question**

6.3 Routine testing is currently recommended for all pregnant women.

True

False

# Hepatitis C

## Prevention & Control Recommendations

## Testing Recommendations

For the following persons, routine testing for HCV infection is not recommended unless they have risk factors for infection.

### Persons for whom routine hepatitis C virus (HCV) testing is not recommended

- Health-care, emergency medical, and public safety workers.
- Pregnant women.
- Household (nonsexual) contacts of HCV-positive persons.
- The general population.

### *Health-Care, Emergency Medical, and Public Safety Workers*

Routine testing is recommended only for follow-up or a specific exposure.

### *Pregnant Women*

Health-care professionals in settings where pregnant women are evaluated or receive routine care should take risk histories from their patients designed to determine the need for testing and other prevention measures, and those health-care professionals should be knowledgeable regarding HCV counseling, testing, and medical follow-up.

### *Household (Nonsexual) Contacts of HCV-Positive Persons*

Routine testing for nonsexual household contacts of HCV-positive persons is not recommended unless a history exists of a direct (percutaneous or mucosal) exposure to blood.

### **Persons for Whom Routine HCV Testing Is of Uncertain Need**

For persons at potential (or unknown) risk for HCV infection, the need for, or effectiveness of, routine testing has not been determined.

**Persons for whom routine hepatitis C virus (HCV) testing is of uncertain need**

- Recipients of transplanted tissue (e.g., corneal, musculoskeletal, skin, ova, sperm).
- Intranasal cocaine and other noninjecting illegal drug users.
- Persons with a history of tattooing or body piercing.
- Persons with a history of multiple sex partners or sexually transmitted diseases.
- Long-term steady sex partners of HCV-positive persons.

***Recipients of Transplanted Tissue***

On the basis of currently available data, risk for HCV transmission from transplanted tissue (e.g., corneal, musculoskeletal, skin, ova, or sperm) appears to be rare.

***Intranasal Cocaine and Other Noninjecting Illegal Drug Users***

Currently, the strength of the association between intranasal cocaine use and HCV infection does not support routine testing based solely on this risk factor.

***Persons with a History of Tattooing or Body Piercing***

Because no data exist in the United States documenting that persons with a history of such exposures as tattooing and body piercing are at increased risk for HCV infection, routine testing is not recommended based on these exposures alone. In settings having a high proportion of HCV-infected persons and where tattooing and body piercing might be performed in an unregulated manner (e.g., correctional institutions), these types of exposures might be a risk factor for HCV infection. Data are needed to determine the risk for HCV infection among persons who have been exposed under these conditions.

***Persons with a History of Multiple Sex Partners or STDs***

Although persons with a history of multiple sex partners or treatment for STDs and who deny injecting-drug use appear to have an increased risk for HCV infection, insufficient data exist to recommend routine testing based on these histories alone. Health-care professionals who provide services to persons with STDs should use that opportunity to take complete risk histories from their patients to ascertain the need for HCV testing, provide risk-reduction counseling, offer hepatitis B vaccination, and, if appropriate, hepatitis A vaccination.

***Long-Term Steady Sex Partners of HCV-Positive Persons***

HCV-positive persons with long-term steady partners do not need to change their sexual practices. Persons with HCV

infection should discuss with their partner the need for counseling and testing. If the partner chooses to be tested and tests negative, the couple should be informed of available data regarding risk for HCV transmission by sexual activity to assist them in making decisions about precautions. If the partner tests positive, appropriate counseling and evaluation for the presence or development of liver disease should be provided.

# Hepatitis C

## Testing for HCV Infection

Consent for testing should be obtained in a manner consistent with that for other medical care and services provided in the same setting, and should include measures to prevent unwanted disclosure of test results to others. Persons should be provided with information regarding

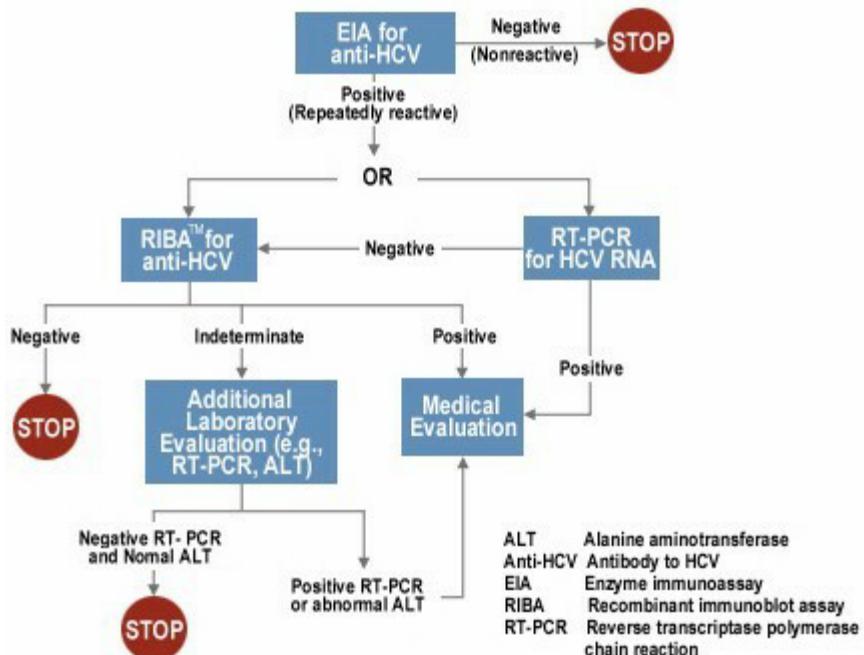

- exposures associated with the transmission of HCV, including behaviors or exposures that might have occurred infrequently or many years ago;
- the test procedures and the meaning of test results; the nature of hepatitis C and chronic liver disease;
- the benefits of detecting infection early;
- available medical treatment; and
- potential adverse consequences of testing positive, including disrupted personal relationships and possible discriminatory action (e.g., loss of employment, insurance, and educational opportunities).

Comprehensive information regarding hepatitis C should be provided before testing; however, this might not be practical when HCV testing is performed as part of a clinical work-up or when testing for anti-HCV is required. In these cases, persons should be informed that a) testing for HCV infection will be performed, b) individual results will be kept confidential, and c) appropriate counseling and referral will be offered if results are positive.

Testing for HCV infection can be performed in various settings, including physicians' offices, other health-care facilities, health department clinics, and HIV or other freestanding counseling and testing sites. Such settings should be prepared to provide appropriate information regarding hepatitis C and provide or offer referral for additional medical care or other needed services (e.g., drug treatment), as warranted. Facilities providing HCV testing should have access to information regarding referral resources, including availability, accessibility, and eligibility criteria of local medical care and mental health professionals, support groups, and drug-treatment centers.

The diagnosis of HCV infection can be made by detecting either anti-HCV or HCV RNA. Anti-HCV for routine testing of asymptomatic persons should include both EIA to test for anti-HCV and supplemental or confirmatory testing with an additional, more specific assay. (Figure 3.) Use of supplemental antibody testing (i.e., RIBA™) for all positive anti-HCV results by EIA is preferred, particularly in settings where clinical services are not provided directly.

**Figure 3. Hepatitis C virus (HCV)-infection-testing algorithm for asymptomatic persons**

Supplemental anti-HCV testing confirms the presence of anti-HCV (i.e., eliminates false-positive antibody results), which indicates past or current infection, and can be performed on the same serum sample collected for the EIA (i.e., routine serology). Confirmation or exclusion of HCV infection in a person with indeterminate anti-HCV supplemental test results should be made on the basis of further laboratory testing, which might include repeating the anti-HCV in two or more months or testing for HCV RNA and ALT level.

In clinical settings, use of RT-PCR to detect HCV RNA might be appropriate to confirm the diagnosis of HCV infection (e.g., in patients with abnormal ALT levels or with indeterminate supplemental anti-HCV test results) although RT-PCR assays are not currently FDA-approved. Detection of HCV RNA by RT-PCR in a person with an anti-HCV-positive result indicates current infection. However, absence of HCV RNA in a person with an anti-HCV-positive result based on EIA testing alone (i.e., without supplemental anti-HCV testing) cannot differentiate between resolved infection and a false-positive anti-HCV test result. In addition, because some persons with HCV infection might experience intermittent viremia, the meaning of a single negative HCV RNA result is difficult to interpret, particularly in the absence of additional clinical information. If HCV RNA is used to confirm anti-HCV results, a separate serum sample will need to be collected and handled in a manner suitable for RT-PCR. If the HCV RNA result is negative, supplemental anti-HCV testing should be performed so that the anti-HCV EIA result can be interpreted before the result is reported to the patient.

Laboratories that perform HCV testing should follow the recommended anti-HCV testing algorithm, which includes use of supplemental testing. Having assurances that the HCV testing is

performed in accredited laboratories whose services adhere to recognized standards of good laboratory practice is also necessary. Laboratories that perform HCV RNA testing should review routinely their data regarding internal and external proficiency testing because of great variability in accuracy of HCV RNA testing.

## patient perspective

*If I was told today of my diagnosis, I would like to be supplied with information concerning the disease, the labs that would be taken and the tests and the results so I could better understand what process I'd be going through and possibly some information concerning support groups--that would be a big help.*

## ? ? ? ? ? study question

7.1 Facilities providing HCV testing should be prepared to:

- A. Provide accurate information regarding hepatitis C
- B. Offer referrals for additional medical care or needed services
- C. Provide counseling for both negative and positive test results
- D. All of the above

# Hepatitis C

## Prevention Messages & Medical Evaluation

HCV-specific information and prevention messages should be provided to infected persons and individuals at risk by trained personnel in public and private health-care settings.

HCV-specific information and prevention messages should be provided to infected persons and individuals at risk by trained personnel in public and private health-care settings. Health-education materials should include a) general information about HCV infection; b) risk factors for infection, transmission, disease progression, and treatment; and c) detailed prevention messages appropriate for the population being tested. Written materials might also include information about community resources available for HCV-positive patients for medical evaluation and social support, as appropriate.

### ***Persons with High-Risk Drug and Sexual Practices***

Regardless of test results, persons who use illegal drugs or have high-risk sexual practices or occupations should be provided with information regarding how to reduce their risk for acquiring bloodborne and sexually transmitted infections or of potentially transmitting infectious agents to others

### ***Negative Test Results***

If their exposure was in the past, persons who test negative for HCV should be reassured.

### ***Indeterminate Test Results***

Persons whose HCV test results are indeterminate should be advised that the result is inconclusive, and they should receive appropriate follow-up testing or referral for further testing.

### ***Positive Test Results***

Persons who test positive should be provided with information regarding the need for a) preventing further harm to their liver; b) reducing risks for transmitting HCV to others; and c) medical evaluation for chronic liver disease and possible treatment.

- To protect their liver from further harm, HCV- positive persons should be advised to
  - not drink alcohol;
  - not start any new medicines, including over-the-counter and herbal medicines, without checking with their doctor; and
  - get vaccinated against hepatitis A if liver disease is found to be present.
- To reduce the risk for transmission to others, HCV-positive persons should be advised to
  - not donate blood, body organs, other tissue, or semen;

- not share toothbrushes, dental appliances, razors, or other personal-care articles that might have blood on them; and

- cover cuts and sores on the skin to keep from spreading infectious blood or secretions.

■ HCV-positive persons with one long-term steady sex partner do not need to change their sexual practices. They should

- discuss the risk, which is low but not absent, with their partner (If they want to lower the limited chance of spreading HCV to their partner, they might decide to use barrier precautions [e.g., latex condoms]); and
- discuss with their partner the need for counseling and testing.

■ HCV-positive women do not need to avoid pregnancy or breastfeeding. Potential, expectant, and new parents should be advised that

- approximately 5 out of every 100 infants born to HCV-infected women become infected (This occurs at the time of birth, and no treatment exists that can prevent this from happening);
- infants infected with HCV at the time of birth seem to do very well in the first years of life (More studies are needed to determine if these infants will be affected by the infection as they grow older);
- no evidence exists that mode of delivery is related to transmission; therefore, determining the need for cesarean delivery versus vaginal delivery should not be made on the basis of HCV infection status;
- limited data regarding breastfeeding indicate that it does not transmit HCV, although HCV-positive mothers should consider abstaining from breastfeeding if their nipples are cracked or bleeding;
- infants born to HCV-positive women should be tested for HCV infection and if positive, evaluated for the presence or development of chronic liver disease
- if an HCV-positive woman has given birth to any children after the woman became infected with HCV, she should consider having the children tested.

■ Other counseling messages

- HCV is not spread by sneezing, hugging, coughing, food or water, sharing eating utensils or drinking glasses, or casual contact.
- Persons should not be excluded from work, school, play, child-care or other settings on the basis of their HCV infection status.
- Involvement with a support group might help patients cope with hepatitis C.

■ HCV-positive persons should be evaluated (by referral or consultation, if appropriate) for presence or development of chronic liver disease including

- assessment for biochemical evidence of chronic liver disease;
- assessment for severity of disease and possible treatment

according to current practice guidelines in consultation with, or by referral to, a specialist knowledgeable in this area

- determination of need for hepatitis A vaccination.

## **NIH CONSENSUS STATEMENT REGARDING MANAGEMENT OF HEPATITIS C (EXCERPTED)**

The NIH "Consensus Statement on Management of Hepatitis C" was based on data available in March 1997. Because of advances in the field of antiviral therapy for chronic hepatitis C, standards of practice might change, and readers should consult with specialists knowledgeable in this area. For more information, visit the National Institute of Diabetes and Digestive and Kidney Diseases (NIDDK) website at

<http://www.niddk.nih.gov/health/digest/pubs/chrnhepc/chrnhepc.htm>

### ***Persons Recommended for Treatment***

Treatment is recommended for patients with chronic hepatitis C who are at greatest risk for progression to cirrhosis, as characterized by

- persistently elevated ALT levels;
- detectable HCV RNA; and
- a liver biopsy indicating either portal or bridging fibrosis or at least moderate degrees of inflammation and necrosis.

### ***Persons for Whom Treatment Is Unclear***

Included are

- patients with compensated cirrhosis (without jaundice, ascites, variceal hemorrhage, or encephalopathy);
- patients with persistent ALT elevations, but with less severe histologic changes (i.e., no fibrosis and minimal necroinflammatory changes) (In these patients, progression to cirrhosis is likely to be slow, if at all; therefore, observation and serial measurements of ALT and liver biopsy every 3-5 years is an acceptable alternative to treatment with interferon); and
- patients aged <18 years or >60 years (note that interferon is not approved for patients aged <18 years).

### ***Persons for Whom Treatment Is Not Recommended***

Included are

- patients with persistently normal ALT values;
- patients with advanced cirrhosis who might be at risk for decompensation with therapy;
- patients who are currently drinking excessive amounts of alcohol or who are injecting illegal drugs (treatment should be delayed until these behaviors have been discontinued for  $\geq 6$  months); and
- persons with major depressive illness, cytopenias, hyperthyroidism, renal transplantation, evidence of autoimmune disease, or who are pregnant.

## ? ? ? ? ? study question

8.1 Individuals with indeterminate test results  
need no additional follow-up.

True

False

# Hepatitis C

## Surveillance

The objectives of conducting surveillance for hepatitis C are to

- identify new cases and determine disease incidence and trends;
- determine risk factors for infection and disease transmission patterns;
- estimate disease burden; and
- identify infected persons who can be counseled and referred for medical follow-up.

Various surveillance approaches are required to achieve these objectives because of limitations of diagnostic tests for HCV infection, the number of asymptomatic patients with acute and chronic disease, and the long latent period between infection and chronic disease outcome.

### ***Surveillance for Acute Hepatitis C***

Surveillance for acute hepatitis C -- new, symptomatic infections -- provides the information necessary for determining incidence trends, changing patterns of transmission and persons at highest risk for infection. In addition, surveillance for new cases provides the best means to evaluate effectiveness of prevention efforts and to identify missed opportunities for prevention. Acute hepatitis C is one of the diseases mandated by the Council of State and Territorial Epidemiologists (CSTE) for reporting to CDC's National Notifiable Diseases Surveillance System.

However, hepatitis C reporting has been unreliable to date because most health departments do not have the resources required for case investigations to determine if a laboratory report represents acute infection, chronic infection, repeated testing of a person previously reported, or a false-positive result. Historically, the most reliable national data regarding acute disease incidence and transmission patterns have come from sentinel surveillance (i.e., sentinel counties study of acute viral hepatitis). As hepatitis C prevention and control programs are implemented, federal, state, and local agencies will need to determine the best methods to effectively monitor new disease acquisition.

### ***Laboratory Reports of Anti-HCV-Positive Tests***

Although limitations exist for the use of anti-HCV- positive laboratory reports to identify new cases and to monitor trends in disease incidence, they potentially are an important source from which state and local health departments can identify infected persons who need counseling and medical follow-up.

Development of registries of persons with anti-HCV-positive laboratory results might facilitate efforts to provide counseling and medical follow-up and these registries could be used to provide local, state, and national estimates of the proportion of persons with HCV infection who have been identified. If such registries are developed, the confidentiality of individual

identifying information should be ensured according to applicable laws and regulations.

### ***Serologic Surveys***

Serologic surveys at state and local levels can characterize regional and local variations in prevalence of HCV infection, identify populations at high risk, monitor trends, and evaluate prevention programs. Existing laboratory-based reporting of HCV-positive test results cannot provide this information because persons who are tested will not be representative of the population as a whole, and certain populations at high risk might be under represented. Thus, data from newly designed or existing serologic surveys will be needed to monitor trends in HCV infection and evaluate prevention programs at state and local levels.

### ***Surveillance for Chronic Liver Disease***

Surveillance for HCV-related chronic liver disease can provide information to measure the burden of disease, determine natural history and risk factors, and evaluate the effect of therapeutic and prevention measures on incidence and severity of disease. Until recently, no such surveillance existed, but a newly established sentinel surveillance pilot program for physician-diagnosed chronic liver disease will provide baseline data and a template for a comprehensive sentinel surveillance system for chronic liver disease. As the primary source of data regarding the incidence and natural history of chronic liver disease, this network will be pivotal for monitoring the effects of education, counseling, other prevention programs, and newly developed therapies on the burden of the disease.

)8785( , 5(&7, 216

To prevent chronic HCV infection and its sequelae, prevention of new HCV infections should be the primary objective of public health activities. Achieving this objective will require the integration of HCV prevention and surveillance activities into current public health infrastructure. In addition, several questions concerning the epidemiology of HCV infection remain, and the answers to those questions could change or modify primary prevention activities. These questions primarily concern the magnitude of the risk attributable to sexual transmission of HCV and to illegal noninjecting-drug use.

Identification of the large numbers of persons in the United States with chronic HCV infection is resource-intensive. The most efficient means to achieve this identification is unknown, because the prevention effectiveness of various implementation strategies has not been evaluated. However, widespread programs to identify, counsel, and treat HCV-infected persons, combined with improvements in the efficacy of treatment, are expected to lower the morbidity and mortality from HCV-related chronic liver disease substantially. Monitoring the progress of these activities to determine their effectiveness in achieving a reduction in HCV-related chronic disease is important.

## ? ? ? ? ? study question

9.1 Surveillance for new cases of HCV infection  
is not useful for evaluating prevention  
efforts.

True

False

## Case Study 1: Natural History & Treatment

A 37-year-old previously healthy woman was notified, by letter, that the blood transfusion she received during a caesarian section in 1989 was from a donor who later tested positive for anti-HCV. She was advised to get tested for hepatitis C and she contacted her primary care physician.

**Her family physician should advise her to do the following at this time:**

1. TRUE FALSE Come in to have a blood specimen drawn for anti-HCV and liver enzyme testing.
2. TRUE FALSE Bring her child (who is now 11 years old) to have a blood sample draw for anti-HCV testing.
3. TRUE FALSE Use condoms when having sex with her husband of 10 years.
4. TRUE FALSE Get hepatitis A vaccine.

She makes an appointment with her doctor, gets tested, and is positive for anti-HCV by EIA and confirmed by RIBA™. Her ALT is within normal limits.

**Considering the natural history of hepatitis C, her physician will want to schedule follow up visits because:**

5. TRUE FALSE She has an 85% chance of being chronically infected with HCV.
6. TRUE FALSE If chronic infection is present, she has a 70% chance of having chronic liver disease.

On the follow-up visit, her physician does PCR for HCV RNA and repeats the ALT. The PCR is negative and her ALT remains normal.

**The physician tells her she may have:**

7. TRUE FALSE Recovered from her infection.

**If she exhibits evidence of liver disease in future follow up, what information about disease progression should she be given?**

8. TRUE FALSE Her risk of progression to cirrhosis might be as high as 50% over 10 to 20 years.
9. TRUE FALSE If she develops cirrhosis, her risk of hepatocellular carcinoma is about 1%-4%.

**If chronic liver disease is diagnosed, what treatment options are available?**

10. TRUE FALSE Only monotherapy with alpha interferon is approved.

**In most situations, what is the preferred regimen?**

11. TRUE FALSE Monotherapy with alpha interferon

## Case Study 2: Chronic HCV Infection In A Health-Care Worker

A 46-year-old previously healthy man who is employed as an emergency room nurse reports to his primary care physician that he is tired and has lost his appetite. After an initial work-up for chronic fatigue syndrome, including a risk factor history that revealed several needle sticks on the job, he is found to be anti-HCV positive by both EIA and RIBA™, and to have an abnormal ALT of 65 (ULN 40). He has a 15-year-old adopted child and has had a monogamous sexual relationship with his wife for 25 years.

**He has a number of questions about how he contracted the infection and what he should do in the future.**

- 12. TRUE FALSE He could have gotten infected at work through a needle stick.
- 13. TRUE FALSE His child should be tested for HCV infection.
- 14. TRUE FALSE He should not continue to work as a health-care worker.
- 15. TRUE FALSE He could have avoided this infection if he had been given immune globulin after needle stick exposure.

**What changes in his behavior are important now that he knows of his chronic hepatitis?**

- 16. TRUE FALSE He should always use barrier precaution when having sex, since HCV is commonly spread by sex.
- 17. TRUE FALSE All close contacts should be vaccinated against hepatitis A and hepatitis B.
- 18. TRUE FALSE He should stop drinking alcohol.
- 19. TRUE FALSE His primary care physician should either consult with or refer him to a specialist knowledgeable about hepatitis C for medical management and possible treatment.

### Case Study 3: Perinatal Transmission of HCV

---

A 40 year old, Gravida 4, Para 3, previously healthy woman is seen for her first prenatal visit. Her last menstrual period was approximately 10 weeks ago.

**Which of the following should prompt testing for evidence of HCV infection?**

- 20. TRUE FALSE History of blood transfusion before July 1992.
- 21. TRUE FALSE Abnormal ALT level
- 22. TRUE FALSE History of injecting-drug use
- 23. TRUE FALSE Pregnancy

The woman reports a history of injecting-drug use when she attended college during the 1970s. Upon testing, she is found to be HCV-positive.

**What should she be told about the risk of HCV transmission to her infant?**

- 24. TRUE FALSE Approximately 5% of infants born to HCV-infected women become infected.
- 25. TRUE FALSE When HCV is transmitted from mother to infant, infection usually occurs in utero.
- 26. TRUE FALSE She should plan on having a C-section.
- 27. TRUE FALSE She should not breast-feed.
- 28. TRUE FALSE Testing for anti-HCV should be considered for her other children.

The woman delivers a healthy baby boy.

**What should she be told regarding management and follow-up for her son?**

- 29. TRUE FALSE The child should be tested for anti-HCV at 6 months of age to determine if he is infected.
- 30. TRUE FALSE A licensed treatment is available if the child is found to be HCV-infected.
